

# Native messaging for strictly confined browsers

Olivier Tilloy – Ubuntu desktop team

# Benefits of firefox packaged as a snap

- Strictly confined: added security layer
- Endorsed and published by Mozilla
- Timely updates
- Runs on old releases (16.04)

# Shortcomings of firefox packaged as a snap

- Browsers interact in many different and creative ways with the system
- Native messaging was broken

# What is native messaging anyway?

- ~~Integration with your favourite instant messaging application~~
- ~~Sending/receiving SMS~~
- IPC between browser extensions and native applications
- Opens up a whole lot of possibilities
- Not necessarily great from a security perspective
- Use cases:
  - GNOME Shell extensions management
  - Password managers (KeepassXC, 1Password, ...)

# Problem statement

- A strictly confined browser cannot enumerate and spawn arbitrary executables on the host system
- How do we address that?

# XDG WebExtensions desktop portal

- WebExtensions portal proposed and implemented by James Henstridge
- D-Bus API for browsers to request launching a native host connector
- The portal
  - Accepts an app name and a unique extension ID as parameters
  - Looks up the corresponding manifest
  - Checks the extension is allowed to run the application
  - Prompts the user
  - Spawns the native connector
  - Passes open FDs to the browser

# Advantages of the portal

- Not specific to one given browser
- Works across confinement technologies (snap, flatpak, ...)
- Available in Ubuntu since 22.04

# Making firefox use the portal

- Two code paths:
  - Legacy (unconfined)
  - Portal (confined, where the portal is available)
- Worked closely with Mozilla engineers
- Coding style and quality standards (tests)
- Pretty large patch (~1800 lines diff)
- Not merged upstream yet
- Cherry-picked in the stable snap last week

CloseSession(handle)

g\_spawn\_close\_pid(...)

# How does this work?

# How does this work?

# Demo

- chrome-gnome-shell (deb)
- KeepassXC (snap)

# Future work

- Get consensus on the portal and get it merged upstream
- Land the firefox patch
- Extract CLI tool to manipulate the permissions db out of flatpak
- Create a UI in the settings app to allow changing those permissions
- Replicate this work for chromium and possibly other browsers
- Remove the KeepassXC warning about snaps

Thank you. Questions?
